ABSTRACT

Objective: To access the level of knowledge of non-medical students about genetic problems related to consanguinity.  
Methodology: A descriptive study was conducted from September 2015 to June 2016 to collect information regarding acquaintance and perceptions about, consanguineous marriages among students of different colleges and universities of Federal Capital. Specially designed performa was used to collect data. The collected data was analyzed by using Statistical Package for Social Sciences (SPSS) software version 16.0. Demographic characteristics of participants were calculated as Mean±SD. Chi-square test was applied to check the level of significance among different categorical variables.  
Results: A total of 424 students were surveyed, out of which 155 (36.6%) were male and 269 (63.4%) were female. The mean age of the study population was 20.39 ±2.44. The data analysis showed only 9.7% of students are fully aware of the problems associated with consanguinity. Girls were found to be more aware as compared to boys (p= 0.05) and among all ethnic groups, Punjabis were found to be more aware (16.9%). In subjects with a history of parental consanguinity and consanguinity in siblings, low level of awareness (8.8% and 8.5% respectively) was found.  
Conclusion: Efforts should be made to increase the knowledge about consanguinity and its association with genetic diseases among non-medical students.  
Key Words: Awareness, Consanguinity, Genetic diseases.

Introduction

Consanguinity, a union between close biological kin, is most common in the Middle East, South and West Asia and North Africa¹. These unions vary widely from the patrilateral parallel consanguineous union in the Middle East to uncle-niece marriages in parts of South India.² Rate of intermarriages varies greatly among a population and is influenced by factors such as religion, education, socio-economic status, geography and local tradition.³,⁴ Due to such unions, gene flow between communities has been highly restricted resulting in a very different inherited disease profile, reflecting local founder effect and gene drift.⁵ The level of homozygosity is 12.5% among first cousin union while the homozygosity level in second cousin marriage is also higher from that in general...
population. Currently, 10.4% of world’s population is married to a second cousin or closer (Coefficient of inbreeding ≥0.0156). The rate of consanguineous marriages in Pakistani population is ~62.7% of which ~80.4% unions are between first cousins. The common reasons being the protection of property, close family ties, familial compatibility, low divorce rate and a part of faith. Prevalence of congenital recessively inherited disorders is high among consanguineous parents. During the last few decades, many rare disease genes have been identified and their chromosomal location has been mapped by studying multiplex consanguineous families. These studies have led to the identification of novel disease-causing gene mutations in Pakistani families showing various abnormal phenotypes such as intellectual disability, eye abnormalities, Deafness and Thalassemia. This study is aimed to access knowledge of adolescent of Islamabad about consanguinity and its probable outcomes.

**Patients and Methods**

A descriptive study was conducted in Capital Territory of Pakistan from September 2015 to June 2016. A structured questionnaire was designed to collect demographic information such as age, gender, ethnicity, residence, native language, and education. Questions were included to evaluate overall knowledge of respondents about consanguinity and prevalence of consanguinity in their families. The study was approved by the Institutional Review Board and informed consent was obtained from all the participants. Students of Higher Secondary School Certification and University level were included in the study. Students of Medical colleges and of secondary school certificate were excluded from the study. The data was collected from students of various departments studying at Quaid-i-Azam University, Air University, Federal Urdu University, International Islamic University, Comsats Institute of Information Technology and various Public-sector colleges of Islamabad. The data were recorded and analyzed by using Statistical Package for Social Sciences version 16.

The questionnaire consisted of 16 questions to assess the level of knowledge of the respondents about consanguinity. Awareness was calculated by using the method described by Jaber et al., with slight modification in numbering. Each question contributed 1 point to the final score. The students who answered 0-8 questions correctly were considered to have a low level of awareness, students who answered 9-12 questions correctly were considered to have a moderate level of awareness and students who responded 13-16 correctly, were considered to have a high level of awareness. Questions were also included to access the acceptability of cousin marriages in families of the respondents and presence of congenital disorders.

**Results**

A total of 424 students participated in this study. The mean age of the participants was 20.39 ±2.44. More than 99% of the participants were Muslims belonging to different ethnic backgrounds. The data analysis showed that 54.5% students have a low level of awareness, 35.8% have a moderate level of awareness while 9.7% of the students have a high level of awareness about the problems associated with consanguinity. Among students surveyed, 66% knew that consanguinity was associated with high incidence of congenital malformations in children. Among these, only 69.6% knew which congenital malformations were associated with consanguinity. (Figure 1)

![Figure 1: Awareness level of the respondents about problems related to consanguinity.](image)

Table 1 represents the demographic characteristics of the participants. Among total participants, 116 (27.4%) were enrolled students of business administration, 163 (38.4%) were from natural sciences, 67 (15.8%) were from applied sciences and 78 (18.4%) of respondents were from higher secondary school education (Table 1).
Table 2 represents demographic characteristics showing an impact on an awareness level. According to the type of degree, education was divided into three groups i.e. intermediate level, undergraduate level and postgraduate level. The data analysis showed that postgraduate students have more awareness (19.8%) as compared to those enrolled in the undergraduate or intermediate programme (3.4% and 12.7%).

Out of the surveyed students, 155 (36.6%) were male and 269 (63.4%) were female. Among the two genders, the percentage of girls with a high level of awareness was found to be significantly greater than that of boys (p=0.00). We also compared the level of education with gender. A number of female enrolled in postgraduate degree was high (31.2%) as compared to boys (27.1%) (Table 2).
However, number of boys enrolled in the undergraduate programme (72.3%) was more as compared to girls (45.7%) (Table 3).

Among all ethnic groups, Punjabi (16.9%) and Sindhi (16.7%) were found to have more awareness (Table 2). Comparison between ethnic groups and education level showed that number of students belonging to pathan community (36.4%) are higher in postgraduate level than other ethnic groups while the number of Urdu speaking students are enrolled more in undergraduate level (58.3%) (Table 3).

Comparison of knowledge between students of consanguineous and non-consanguineous parents showed that even children of consanguineous parents had low awareness. (Table 2).

Students whose one or more siblings were married within the family have relatively less awareness (8.5%) as compared to those whose siblings were not married within family or cast (9.8%). The students were questioned about the presence of any congenital disorder in their siblings such as deafness, mental retardation or blindness. Of the 424 respondents, 54 (12.7%) reported the presence of at least one disorder in their siblings. Students who had siblings with congenital abnormality showed a significantly lower level of knowledge as compared to those without such abnormalities (p=0.00) (Table 2).

### Discussion

The study results showed that almost half (54.2%) of the students were unaware of the problems associated with consanguinity. Among the two genders, girls were found to be more aware (13.4%) as compared to boys (3.2%). The probable reason for this finding can be that more female were enrolled in post-graduation level as compared to male. This finding is in line with the findings of similar studies conducted on Saudi adults, Egyptian and Israeli Arab Population.17-19 Students belonging to urban and rural areas showed a lower level of awareness as compared to those belonging to suburban areas. Among all ethnic groups, Punjabis showed more awareness as compared to others. A number of Sindhi and Balochi respondents were less in our target population. Extending similar studies in these populations can give more details. Studies conducted in Azad Kashmir showed an increase in consanguinity in literate subjects.20

Consanguinity among parents and sibship was found to be associated with lower level of awareness. Same trends were observed in the comparison between awareness level and presence of congenital malformation. Our findings are in line with the studies conducted on Israeli, Arab adolescent.17 The comparison between parental consanguinity and education level of participants showed that percentage of children belonging to non-consanguineous parents enrolled in the postgraduate level were more (30.4%) as compared to consanguineous parents (28.9%). Ghafoor et al.,21 showed that even level of awareness about thalassemia among parents of diseases patients was low. As parents are the primary source of information for children lack of awareness of parents can be a probable reason for unawareness in their children despite the presence of consanguinity and congenital disorders.

### Conclusion

Our finding showed an overall low of awareness about problems associated with consanguinity among non-medical students. We suggest that this topic should be considered while planning educational curriculum in secondary and higher secondary education system so that they can educate their family members and thus can
